1           COLOR-CALIBRATION SENSOR WITH AUXILIARY CARRIAGE  
2           FOR INCREMENTAL PRINTING

3

4           ABSTRACT OF THE DISCLOSURE

5

*Sub B9*

6           In one form of the invention, one sensor determines  
7       mutual alignment of pens; a second sensor measures color  
8       of dots formed on a print medium by the pens. Another  
9       form has two carriages — one moving pens to mark on a me-  
10      dium and the second used to refine quality of images pro-  
11      duced. In a third form, a sensor measures color of test  
12      patterns by one or more pens; a hood — generally around  
13      the sensor laterally relative to a sensing direction —  
14      excludes ambient light from the sensor during measuring; a  
15      mechanism advances the hood along the sensing direction  
16      toward the patterns. In a fourth form, a pen ejects mul-  
17      tiple liquid-ink drops onto a medium, and a sensor infre-  
18      quently measures color of resulting dots — only when the  
19      pen is not forming images. In this form a door protects  
20      sensor optics from coating by ink aerosol when the sensor  
21      is not in use, including whenever the pen is writing; a  
22      mechanism opens and closes the door before and after sen-  
23      sor use. In a fifth form, a mechanism advances a color-  
24      property-measuring sensor into contact with a medium bear-  
25      ing test patterns. In a sixth form, a flashlamp in the  
26      printer illuminates test patterns for measurement — at an  
27      intensity high enough to make ambient light essentially  
28      insignificant, and preferably for a time short enough to  
29      make lamp energy usage and heating negligible. In a sev-  
30      enth form, a moving carriage positions a sensor over test  
31      patterns and at least one colorimetric reference target is  
32      exposed to the sensor. The forms are best used together  
33      and are subject to many important preferences.
